Sea island located in the southern coast of Iceland, the island was formed from below the sea surface due to eruptions of a volcano. The process was recorded in 1963 fishing vessels through aborted a troller sealing the Iceland's body a column of smoke rising from the sea surface. The ship's captain thought in my be a boat on fire, and 10 his vessel to investigate. What they found was an island being born. The eruption ultimately lasted three and a half years, ending in June 1967. The birth of this new landform wasn't the end of Susie's story. In the spring of 1965, only a few scientists are permitted to land on Tootsie. The only way anyone else has seen it closely is from a small plane. This allows natural ecology goes succession for this island proceed without outside interference. The first a higher plant was discovered at the shoreline is a flower caught sea rocket fly arrived on Susi soon after its formation, and it was first detected in 1964. They're carried to this island by a wanes and their own power. Scientists are also shocked. The large area was covered by a wider ground rise in 1974. Scientists to half of it for analysis and discovered 663 plant species in the 1960s regular bird observations were maintained on to see these were directed primarily as stating migrants in spring and autumn. Their importance of carrying pioneering plant seeds to these Island is a new investigation. A year after the eruption started, a number of bacteria species increased rapidly to 35 on to about 1970s and then level off and has increased slowly since it was a number of speeches fluctuating around a 40 to 50 speeches recorded on these assembling occasion in 1990s. The same survey was repeated the following year. Now also including the registration of habitat choice, and habitat abundance for each species. In 1971 36 species are also found, of which 21 New to the island, including the first deliver what speeches for the first time scientists the founder green vegetation mountings form the thick carpet in the western most the lightest, the greater. You are never too old to learn. It is sad, but you must admit the some kind of information sounds more like a joke. Like the findings of photo Ansu see

an island only 39 years old. The fossils were obtained as early as five years after eruption. radio observations suggest that very energetic particles produced the violent eruption is still active. The volcanic ash samples are collected from locations by scientists also indicate this island is still on the move of new formation. Sufi is situated in a region of extremes in winter Weather and wave climate. The violent explosions caused by meeting of lava and sea water meant that this island consisted of loose pile of mechanical lock by storms during the winter. Wave data near Susi have been recorded by maritime and administration since 1998. This island is unlikely to disappear entirely in the near future investigation assuming that the rate of erosion will be slow suggests that this island will last for at least the many centuries. human impact is a small hut, which is used by researchers while staying on this island
